Using PHP's built-in temp directory for database connection - best practice? I've seen many blog posts and PHP websites claiming that it is dangerous to use the system's default temp directory to store a database connection (such as MySQL, SQLite) as there is potential for a race condition. So, instead, you need to use a temp directory and create your own database connections via `file_get_contents()` with something like this: `define('DATABASE_URL','mysql://root:root@localhost/tempdb'); $db = new PDO(DATABASE_URL); $db->setAttribute(PDO::ATTR_EMULATE_PREPARES, false); $db->setAttribute(PDO::ATTR_ERRMODE, PDO::ERRMODE_EXCEPTION); $db->setAttribute(PDO::ATTR_DEFAULT_FETCH_MODE, PDO::FETCH_OBJ);` Or, you can use `PDO::MYSQL_ATTR_DIRECT_QUERY`. My question is, why does this need to be done? Is it not sufficient to just create a temp directory on your server and use it for everything including PHP files? The only reason I can think of is that one needs to access the temp folder to delete the files which are used to create the database connection... A: It is not a sufficient solution, because it is not a real directory (if it is, then Apache's /tmp is really an ordinary directory and you can put databases there). Also, by creating your own directory, you don't have the lock system from your operating system, and you can't rely on
