Q: How does an operating system handle threads? Many operating systems support the concept of threads. Usually, operating systems with "real" threads support multiple threads, but operating systems with "pseudo" threads can only run one thread. This question has been answered here (which works!), but I am now confused about the true way to read and write from shared memory. Consider the following example. I'm using Linux. Let's assume we have a program A and we want to communicate with it. We have an object in memory, which is in turn backed by some data which we want to share with A. Thus, we define a struct A_data and create an object of this type. If we want to share some data with A, we just have to create an object of type A_data and pass the pointer to it to A. Then, A is free to use the data as it sees fit. Is this a correct way of handling threads? The linked answer mentions a flag which can be set to force an update on 09e8f5149f
